Less known, „hidden“ settings and tricks for advanced users.

Feature	From version	Description
Influence the local nuclet identifier (migration 3.x4.0)	4.0	In the nuclet description set <code>migration_04_00_00.nuclet.preferred.local.identifier=C3P0</code> . The identifier has 4 characters (A–Z0–9_, starting with an uppercase letter). Only the 3.x4.0 migration reads it; it can be deleted afterwards. On conflicts ("preferred") only one nuclet gets the desired identifier.
Set the local nuclet identifier on import	4.0	Import an empty nuclet „shell“, set the desired value in <code>T_AD_APPLICATION.STRLOCALIDENTIFIER</code> , then import the real nuclet.

 **Caution**

These interventions require database knowledge and should be used carefully.
